Shared protected Clifford operations; different non-Clifford protocols

STAR: inject the requested angle

Start at $\varphi = \theta$; use $|A_\varphi\rangle = e^{-i\varphi Z}|+\rangle$

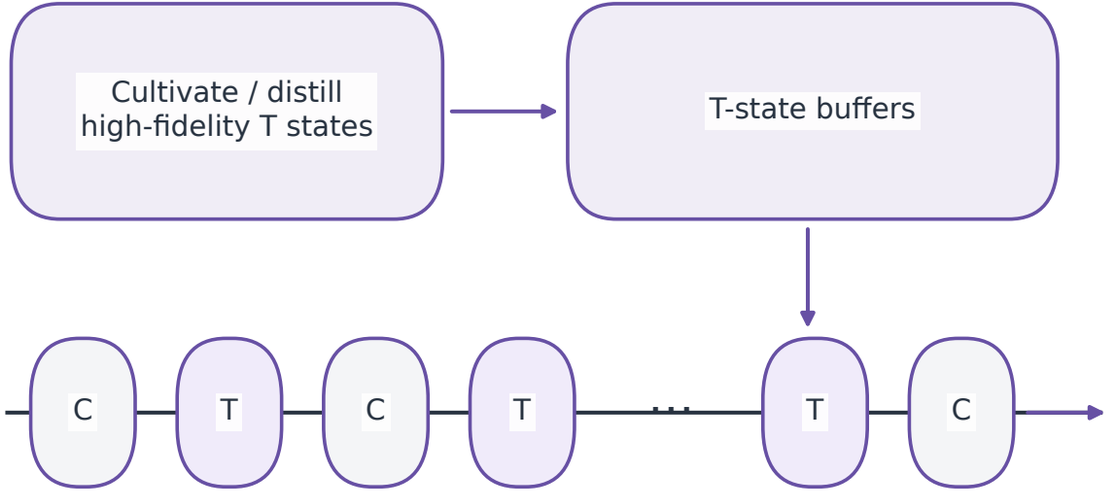

Ideal sign retries: mean 2 teleportations

Residual rotation noise → PEC sampling

FTQC: synthesize the requested angle

Approximate $e^{-i\theta Z}$ to a chosen synthesis tolerance

C: Clifford operations; T includes inverse T gates

Generic rotation: $N_T = O(\log(1/\varepsilon_{\text{syn}}))$

State errors + logical faults enter the bias budget

Hybrid: analog injection for small angles + high-fidelity T states for fixed π/8 rotations. Flow diagrams; not equal-duration schedules.
